equilibrium, the algebraic sum of the moments of all the individual forces about any point is equal to zero.

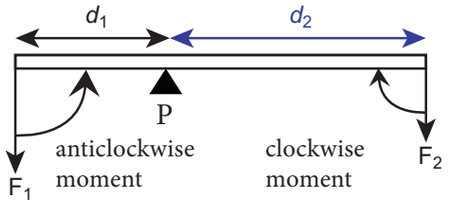

**Figure 1.5** Principle of moments

In the illustration given in figure 1.5, the force $F_1$ produces an anticlockwise rotation at a distance $d_1$ from the point of pivot P (called fulcrum) and the force $F_2$ produces a clockwise rotation at a distance $d_2$ from the point of pivot P. The principle of moments can be written as follows:

Moment in clockwise direction = Moment in anticlockwise direction

$$F_1 \times d_1 = F_2 \times d_2 \quad \ldots\ldots\ldots \quad (1.4)$$

## 1.5 NEWTON'S SECOND LAW OF MOTION

According to this law, "**the force acting on a body is directly proportional to the rate of change of linear momentum of the body and the change in momentum takes place in the direction of the force**".

This law helps us to measure the amount of force. So, it is also called as '*law of force*'. Let, 'm' be the mass of a moving body, moving along a straight line with an initial speed 'u' After a time interval of 't', the velocity of the body changes to 'v' due to the impact of an unbalanced external force F.

Initial momentum of the body $P_i = mu$

Final momentum of the body $P_f = mv$

Change in momentum $\Delta p = P_f - P_i$

$= mv - mu$

By Newton's second law of motion,

Force, F $\propto$ rate of change of momentum

F $\propto$ change in momentum / time

$$F \propto \frac{mv - mu}{t}$$

$$F = \frac{km(v - u)}{t}$$

Here, k is the proportionality constant. k = 1 in all systems of units. Hence,

$$\mathbf{F = \frac{m(v - u)}{t}} \quad (1.5)$$

Since, acceleration = change in velocity/ time, a=(v-u)/t. Hence, we have

$$\mathbf{F = m \times a} \quad (1.6)$$

Force = mass × acceleration

No external force is required to maintain the motion of a body moving with uniform velocity. When the net force acting on a body is not equal to zero, then definitely the velocity of the body will change. Thus, change in momentum takes place in the direction of the force. The change may take place either in magnitude or in direction or in both.

Force is required to produce the acceleration of a body. In a uniform circular motion, even though the speed (magnitude of velocity) remains constant, the direction of the velocity changes at every point on the circular path. So, the acceleration is produced along the radius called as *centripetal acceleration*. The force, which produces this acceleration is called as centripetal force, about which you have learnt in class IX.

**Units of force:** SI unit of force is newton (N) and in C.G.S system its unit is dyne.

**Definition of 1 newton (N):** The amount of force required for a body of mass 1 kg produces an acceleration of 1 m $s^{-2}$, **1 N = 1 kgms$^{-2}$**

**Definition of 1 dyne:** The amount of force required for a body of mass 1 gram produces an acceleration of 1 cm $s^{-2}$, **1 dyne = 1 gcms$^{-2}$;** also **1 N = $10^5$ dyne.**
